TITLE: Thermomechanical treatment of heat-resistant martensitic steel	
SOURCE: AN SSSR. Izvestiya. Metally, no. 5, 1965, 143-148	
TOPIC TAGS: steel, heat resistant steel, martensitic steel, mechanical heat treatment, plastic deformation, yield stress, tensile stress /EI961 steel	
ABSTRACT: Heat-resistant EI961 steel (0.14% carbon, 10.8% chromium, 1.75% nickel, 1.65% tungsten, and 0.26% vanadium) has been tested for the effect of thermomechanical treatment (TMT). Three variants of TMT were used: 1) high-temperature thermomechanical treatment (HTMT) — plastic deformation at 900—1050°C followed by cooling; 2) low-temperature thermomechanical treatment (LTMT) — austenitizing at 100°C, cooling to 600°C, plastic deformation, and cooling; and 3) combined high- and low-temperature treatment (HLTMT) — plastic deformation at 1050°C, cooling, tempering at 580°C for 3 hr, plastic deformation at 600°C, and cooling. Preliminary experiments showed that optimum reductions for HTMT or LTMT are 20—30% and for HLTMT, 50% at 1050°C and 7—10% at 600°C. All three variants of TMT considerably improved strength and heat resistance without a significant decrease in ductility. The room-temperature tensile and yield

Temkina.

PURPOSE: This book is intended for engineers, architects, and  
personnel of building-material industries.

COVERAGE: The author discusses a new building material, polymer-  
cement concrete, which is a mixture of cement and latex, or

Card 1/6

SOV/5128

Polymer-Cement Concrete

cement and a polymer emulsion. Properties of the new material and its production methods are discussed. The polymer and mineral binder which are used are examined from the standpoint of their effect on properties of the polymer-cement concrete. Considerable attention is given to problems of the stabilization of mixtures. Soviet and other experience gained in the constructional application of polymer-cement concrete is described. According to the Foreword, this booklet is the first attempt to summarize the principal Soviet and non-Soviet contributions to the field as well as the results of scientific research and experiments carried out in the polymer-concrete laboratory of the Vsesoyuznyy nauchno-issledovatel'skiy institut novykh stroitel'nykh materialov Akademii stroitel'stva i arkhitektury SSSR (All-Union Scientific Research Institute of New Building Materials of the Academy of Construction and Architecture USSR), under the supervision of the author, with V. M. Kalashnikova, Senior Scientific Worker, and V. L. Smelyanskiy, Engineer. The research was conducted under the scientific guidance of B. G. Skramtayev, Professor, Member of the Academy of Construction

TITLE: Polymer-cement Materials

PERIODICAL: Plasticheskiye massy, 1960, No. 9, pp. 4 - 7

TEXT: Using polyvinyl-acetate cement concrete as an example, the authors deal with the basic requirements polymer latices and emulsions have to meet for the preparation of polymer cement. The polyvinyl-acetate emulsion prepared in the presence of polyvinyl alcohol is very stable and does not coagulate on mixing with cement. Latex mixtures may be stabilized temporarily by the addition of electrolytes. It was found that the stabilizers and emulsifiers used in polymerization affect not only the mixing of latex with cement, but also considerably the setting of cement. The ratio of polymer and cement was found to be the determining factor for the physicomechanical properties of the polyvinyl-acetate cement concrete. At a ratio of polymer:cement=0.2, the impact resistance of concrete is five times that of ordinary concrete. The following principles must be observed in the choice of latices or emulsions: a) The existence of adhesiveness and

Card 1/2

87656

Polymer-cement Materials

S/191/60/000/009/001/010  
B013/B055

cohesiveness during the mixing of cement. b) Polymer emulsions must contain stabilizers to prevent their coagulating on mixing with cement. c) Emulsifiers and stabilizers must not have a detrimental effect on the setting of cement. It would be desirable if emulsions contained substances to improve setting. d) Tests using dibutyl phthalate showed that polymers of maximum hardness and strength must be applied for the preparation of polymer-cement concretes with high compressive, flexural, and tensile strength. e) The use of polymers resistant to water and aggressive mediums enables improvement of polymer-cement concrete properties. The preparation of mixtures of polymer emulsions and cements is extremely simple and in no way different from the usual preparation of ordinary concrete. This will permit the rapid introduction of polymer cements in construction engineering. There are 8 figures and 14 references: 8 Soviet, 3 German, 2 US, and 1 British.

TITLE: Kinetics of structure formation in polymer cements

PERIODICAL: Kolloidnyy zhurnal, v. 23, no. 5, 1961, 632 - 637

TEXT: The effect of emulsifiers and stabilizers on the hardening of cement is studied in this paper. The technique developed by the kafedra kolloidnoy khimii Moskovskogo universiteta (Department of Colloid Chemistry) of Moscow University (Ref.10: P. A. Rebinder, N. A. Semenenko, Dokl. AN SSSR 64, 385, 1949) was used to study the hardening process, i.e., the kinetics of structure formation in the cement suspension with added stabilized aqueous polymer dispersions and additional stabilizers (colloids, surfactants, and electrolytes). The aqueous polymer and stabilizer dispersions are divided into four groups with respect to their effect on structuration, i.e., 1) electrolytes used as latex stabilizers ( $K_2CO_3$ ,  $Na_2CO_3$ ,  $K_2CO_3 + Na_2CO_3$ ,  $NaH_2PO_4$ , and  $K_2SiO_3$ ); 2) surfactants and colloids (polyvinyl alcohol (PVA), Nekal (NK), Nekal and  $K_2CO_3$ , ammonium caseinate (AC), sodium alginate (SA)), X

Card 1/5

Kinetics of structure...

26281

B124/B101

NK (emulsifier) and AC (stabilizer)); 3) aqueous polymer dispersions ( (a) polyvinyl acetate emulsion (PVAc-L) containing 7% PVA; (b) polyvinyl acetate emulsion (PVAc-N) with 3% Nekal; (c) divinyl styrene latex (CKC-65 ГП (SKS-65 GP) ) with 3% Nekal; 4) aqueous polymer dispersion (PVAc-L emulsion) with  $\text{CaCl}_2$  as a hardening accelerator of the cement. The aqueous dispersions were added to the cement suspension at a ratio of the weight of the dry polymer (P) to that of the cement (C) of 0.2. A water-cement ratio of W/C = 0.3 was used in all experiments.  $\text{CaCl}_2$  was taken in a concentration of 3% related to the cement. Portland cement with the composition  $\text{C}_3\text{S} = 34\%$ ,  $\text{C}_2\text{S} = 34\%$ ,  $\text{C}_3\text{A} = 11\%$ ,  $\text{C}_4\text{AF} = 12\%$  was investigated; the

specific surface determined with the Tovarov device was  $3650 \text{ cm}^2/\text{g}$ . While an induction period (slow rise of the resistance to plastic deformation) and coagulated-structure formation during the first 3.5 hours, followed by a hardening period with intensified crystalline-structure formation occurs in pure cement suspensions, a considerable change in the structuration kinetics is established in the presence of electrolytes with hardening being influenced

Card 2/5

Kinetics of structure...

S/069/61/023/005/008/008  
B124/B101

rather by the anions than by the cations of the electrolyte. The efficiency of the anions decreases in the sequence:  $\text{CO}_3^{2-} > \text{SiO}_4^{3-} > \text{H}_2\text{PO}_4^-$ . The effect of a two-component stabilizer system introduced into the cement suspension is equal to that obtained from the combined effects of the components (Fig.2). Fig.3 shows the effect of aqueous polymer dispersion on the resistance of the polymer cement suspension to plastic deformation. AC is an unsuitable stabilizer for rapidly hardening mixtures which yields, however, high-stability products, while electrolyte-stabilized cements are stable only for a limited time. Potassium or sodium caseinates accelerate the hardening of polymer cement mixtures. When a PVA-stabilized emulsion is used, very rapidly hardening systems are obtained. The hardening rate can be further increased by adding 1%  $\text{CaCl}_2$ . O. I. Luk'yanova and S. A. Daryusina (Ref.7: Kolloidn. zh., 20, 628, 1958) are mentioned. There are 5 figures, and 11 references: 9 Soviet and 2 non-Soviet. The two references to English-language publications read as follows: K. E. Clare, P. T. Sherwood, J. appl. Chem. 4, 625, 1954; W. G. Wren, Trans. Inst. Rubber Ind., 13, 189, 1937.

AUTHOR: Cherkinskiy, Yu. S. (Candidate of technical sciences)

TITLE: Polymer-cement concretes of cationic chloroprene latex

SOURCE: Beton i zhelezobeton, no. 12, 1964, 546-548

TOPIC TAGS: concrete, construction material, polymer, cationic latex, chloroprene latex / OP 7 surface active substance, Dupont latex No. 950

ABSTRACT: The author discusses the use of latex No. 950 (Dupont Company, U.S.A.) as an additive in concrete. The latex is described as consisting of 50% dry ingredients, having a unit weight of 1.10 g/cm<sup>3</sup> (at 25°C), a pH of 9.3, mean particle size 0.1 μ, and surface tension 44 dynes/cm<sup>2</sup>. Experimental tests were conducted using portland cement of the following percentage content: SiO<sub>2</sub> - 23.72; Al<sub>2</sub>O<sub>3</sub> - 5.30; Fe<sub>2</sub>O<sub>3</sub> - 2.81; CaO - 61.21; MgO - 1.67; SO<sub>3</sub> - 2.70; and 1.90 trace elements. River sand with mean grain diameter 0.26 mm was also used. Nonionic surface active substance OP-7, added in 6% proportion to the polymer, was found to delay coagulation for a period of two hours. The kinetics of hardening

Card 1/2

L 24129-65

ACCESSION NR: AP5001784 /

were measured by the method of Academician P. A. Rebinder. Results showed that introducing latex No. 950 into the cement increases the induction period and slows latex-cement hardening. A one percent quantity of calcium chloride added to the mix resulted in faster mix hardening in the first days of cure. The effect of surface-active substances on kinetic structure formation was also studied. Addition of alkamine (0.6%) somewhat slows the processes of structure formation. The effect of several additives upon hardening rate is shown in a plot, and creep settlement rates for several consistencies were plotted. The author suggests the use of polymer concrete from cationic chloroprene latex as surfacing material in construction. Orig. art. has: 4 figures and 4 tables.

Text Data

Coverage: The production of mineral wool and mineral wool products is described.  
Raw materials, equipment, planning and operation of plants for the  
production of mineral wool are discussed. The final chapter is devoted to  
the uses of mineral wool products as sound and thermal-insulating materials  
in construction and industry. Only Russian references are cited.

*Method of determining the viscosity of blast-furnace slags and minerals. D. A. Charkov. Zavodskay Lab., 21 [12] 1461-63 (1955); abstracted in J. Iron Steel Inst. (London), 184 [4] 460 (1956).—A method recently developed for glass and adapted to viscosity determinations of blast-furnace slags is described. The results are obtained in terms of the viscosity of a standard material. The powdered slag (1.8 to 1.9 g/cm<sup>3</sup>) is moistened and pressed at 50 kg/cm<sup>2</sup> into a cylinder 10 mm in diameter and height. The cylinder and a closely similar one of the standard material are placed vertically on the horizontal platform of low plates by refractory plates in a furnace. After soaking at the required temperature for 30 to 60 min., the furnace is switched off. The increases in areas of contact of the two materials with the plates are determined, and the viscosities are calculated therefrom by a simple equation.*

Title: Effect of Tar Compounds on the Rate of Autoxidation of Cracking  
Kerosenes

Original  
Periodical: Zh. prikl. khimii, 1955, 28, No 12, 1332-1338

Abstract: A study of the effects on autoxidation of cracking kerosenes of  
products that accumulate in the fuel during the process of autoxi-  
dation. For this purpose from cracking kerosenes produced from  
petroleum of first and second Baku, were isolated: tars of acidic  
nature (TAN), tars of neutral nature (TNN), compounds of phenolic  
type (PC), acids and hydroxy acids (HA). The isolated and charac-  
terized compounds were added to the initial cracking kerosenes.

Abst Journal: Referat Zhur - Khimiya, No 19, 1956, 62579

Abstract: Effects of additions to cracking kerosenes on the tendency of the latter to undergo oxidation were evaluated on the basis of oxygen absorption, changes in acid number and actual tars, on oxidation of the fuel for 2.5 hours with air oxygen at 125°. It is shown that TAN and HA are strong initiators of autoxidation of the fuel, and TNN in amounts found in the fuels have an inhibiting effect on the reaction of autoxidation. The inhibiting effect being increased with increase of their amount in the fuel. PC present in cracking kerosenes of first and second Baku have a slight inhibiting effect on autoxidation of fuels. Described is the procedure of isolation of oxidation products from cracking kerosenes.

TITLE: Electrical activity of the cerebral cortex <sup>22</sup> in monkeys of various ages in response to rhythmical light flashes

SOURCE: Fiziologicheskiy zhurnal SSSR, v. 51, no. 4, 1965, 431-440

TOPIC TAGS: cerebral cortex, electrophysiology, experiment animal, EEG

ABSTRACT: The dynamics of the response to rhythmic light flashes were studied on Macacus baboons, Rhesus macaques, and green guenons from the earliest days of life to old age on the basis of EEG measurements carried out on the occipital part of the cerebral cortex. In the first days of life the macaques and baboons showed a clear response to light flash frequencies of 5-10 per sec and a weaker response to frequencies of 15 per second, while guenons responded to a wider range of frequencies, i.e., 5-20 per second. From the 2d week of life, animals of all three species responded to frequencies of 5-24 per second with the highest amplitude and

greatest regularity of oscillations in the rhythm imposed on the EEG shown in the range of 5-10 light flashes per second. With increasing age (2 wks to 6-7 months) all indices characterizing the response to rhythmic light flashes increased in magnitude. At ages of 3-4 to 8-10 months, an influence of the background electric activity on the reaction to light flashes was observed. Beginning with the age of 6-8 months, the amplitude of the imposed rhythms decreased. The imposed rhythms in the EEG became stabilized towards the age of 2 years. At this age, there was a clear response to light flash frequencies in the range of 5-24. This corresponded approximately to the range of response in human adults (6-20 flashes per second). At all ages, guenons were more sensitive than baboons and macaques as far as their response to rhythmic light flashes was concerned. Experiments on macaques and baboons indicated that the response to light flashes decreased considerably at the age of 15-20 years; it disappeared entirely at an advanced old age (towards 27 years). The results of the experiments did not indicate that the optimum response, in accordance with a widespread impression to that effect, takes place when the frequency of light flashes coincides with the prevalent frequency of EEG oscillations. Title : Methallyl Chloride as a Fumigant for the  
Disinfestation of Seeds.  
Orig Pub : Mukomol.-elevat. prom-st, 1956, No 7, 9-10.  
  
Abstract : The suitability of methallyl chloride (I)  
for the fumigation of grains has been in-  
vestigated. An application dose of 15 gms/m<sup>3</sup>  
is required for the complete extermination  
of the barn weevil (BW) for a contact time  
(CT) of 24 hrs in an empty hermetically  
sealed glass vessel; the corresponding dose  
for a CT of 48 hours is 8 gms/m<sup>3</sup>. The com-  
plete extermination of the larvae and pupae

of the BW within 24 hours is achieved with an application dose (AD) of 11 gms/m<sup>3</sup> of I; the corresponding dose for a CT of 48 hours is 8 gms/m<sup>3</sup>. 100% effectiveness against the BW in the egg stage is achieved with AD of 9 gms/m<sup>3</sup> and 5 gms/m<sup>3</sup> of I for CT of 24 and 48 hours, respectively. A 100% kill rate for the BW in grains at a CT of 48 hours is achieved with an AD of 25 gms/m<sup>3</sup> I; the dose for a CT of 72 hours is 15 gms/m<sup>3</sup>. Complete effectiveness is achieved against the butterfly of the meal worm for a CT of 24 hours with an AD of 11 gms/m<sup>3</sup> I; the AD for a CT of 48 hours is 6 gms/m<sup>3</sup> I; the corresponding doses for the rice weevil

are 7 gms/m<sup>3</sup> and 3 gms/m<sup>3</sup>. I has maximum  
toxic action at 20°. Treatment with I does  
not impair the seed properties of smooth and  
scaly grains.
